Overview

This document defines how translation is addressed in DA for TFS. It covers how DA's translation app works, how TFS's existing translation workflow maps to DA, the translation service approach, and how each functional translation requirement is met.

1. How Translation Works in DA

DA includes a built-in translation app available to authors. Translation is managed through projects — authors select the pages they want translated, configure the target languages, and submit to a connected translation service. Translated content returns and is placed in the correct language folder in the content hierarchy.

Author Workflow

Step	What the Author Does
Create project	Open the translation app and create a new translation project
Add content	Add the URLs of pages to be translated
Validate sources	Confirm the source content is ready for translation
Select languages	Choose the target languages for this project
Submit	Send content to the configured translation service

Monitor	Track translation progress from the project dashboard
Review	Review translated content once it returns

This project-based approach gives authors visibility and control over what is translated and when — translation is always a deliberate, author-initiated action.

2. TFS Translation Workflow

How TFS Translates Today

TFS translates content selectively — not every page is translated. The translation source for each local language variant is the **country-level English** page, not the regional English. For example, Brazil English (EN-BR) is the source for Brazil Portuguese (PT-BR). This is a one-to-one translation at country level.

The current process is entirely manual:

1. Authors export page content as XML from AEM
2. XML is submitted to WordBee (TFS's translation management system)
3. WordBee returns the translated XML
4. Authors import the translated XML back into AEM

When a page is successfully translated, two properties are updated on the page: **translation status** and **translation date**. These properties are used by the system to determine whether to display a translated Experience Fragment or fall back to the English version.

How TFS Translates in DA

The translation source remains the same — country English continues to be the source for its local language variant. Selective translation continues — authors choose which pages to submit for translation. The project-based workflow in DA's translation app replaces the manual XML export and import process.

3. Translation Service — WordBee

Current State

TFS currently has no API connection to WordBee. The process is entirely manual — XML is exported, sent to WordBe, and the translated output is imported back into AEM.

DA Translation Service Approach

DA supports Google Translate out of the box. For third-party translation services, DA can connect to a custom provider through a connector, provided that the translation service exposes APIs for integration.

For WordBee specifically — **whether WordBee exposes the APIs required for a DA connector is to be confirmed**.

Scenario	Outcome
WordBee exposes APIs	A connector can be configured, allowing authors to submit content directly from the DA translation app to WordBee electronically. Translated content returns automatically — no manual export or import.
WordBee does not expose APIs	The current manual process continues — content is exported, sent to WordBee, and returned content is imported into DA. The DA translation app manages the project and tracking, but the exchange with WordBee remains manual.

4. Translation Configuration

Translation behavior in DA is configurable through a configuration file maintained by administrators. The key options relevant to TFS are:

Translate behavior Controls how translated content is handled when it returns from the translation service.

- **Overwrite** — replaces existing content with the translated version. Suitable when the translated page should fully reflect the source with no local retention.
- **Merge** — combines the translated content with the existing page, requiring an author review to confirm which content to keep. Suitable when certain sections of a page may have been locally maintained and should not be overwritten.

Staging Controls whether source content is staged in a separate area before being sent for translation. Staging allows authors to prepare and adjust source documents without affecting the live content before translation begins.

5. Functional Use Cases — How Each Is Addressed

Use Case 1 — Country English as Translation Source

What TFS does today: Country English is the immediate translation source for that country's local language. Brazil English (EN-BR) → Brazil Portuguese (PT-BR). Translation is selective and initiated manually. The translated page receives a translation status and translation date property that the system uses to determine Experience Fragment display.

How it works in DA: The same translation source relationship is maintained — country English remains the source for its local language variant. Authors use the DA translation app to create a project, add the country English pages they want translated, and submit to the translation service. The selective nature of translation continues — authors choose what to translate and when.

The translation status and translation date properties are **not required in DA**. In AEM, these properties drove the XF best-match resolver to decide whether to show a translated Experience Fragment or fall back to English. In DA, the MSM hierarchy handles this natively — if a translated fragment does not exist at the local level, the hierarchy cascades up to the parent English level automatically. There is no resolver to feed with a status property.

Status: Supported in DA. Translation app replaces manual XML export/import. Translation status properties not carried forward.

Use Case 2 — XF Translation

What TFS does today: Experience Fragments are translated separately from pages. The XF translation workflow is independent — XFs are exported, translated, and imported through a separate process from page translation. This creates two parallel translation workflows that must be managed independently.

How it works in DA: In DA, fragments are regular documents — they are not a separate content type. The same translation app and the same translation project that handles pages also handles fragments. There is no separate XF translation workflow. Authors add fragment URLs to a translation project alongside page URLs and submit them together.

This unifies what today requires two separate processes into a single consistent workflow.

Status: Unified in DA. No separate XF translation workflow required.

6. Summary

Capability	AEM — Today	DA — Target
Translation initiation	Manual XML export from AEM	Author-initiated project in DA translation app
Translation source	Country English → Local Language	Same — country English remains the source
Selective translation	Yes — authors choose what to translate	Yes — authors select pages in project
Translation service exchange	Manual XML sent to and received from WordBe	Connector-based if WordBee APIs available; manual otherwise
XF translation	Separate workflow from page translation	Unified — same project handles pages and fragments
Translation status / date properties	Required — drives XF best-match resolver	Not required — MSM hierarchy handles fallback natively
